## General definitions

**Table 1** lists some general definitions relevant for this document.

**Table 1:** General definitions.

Item	Definition
XCO <sub>2</sub>	Column-averaged dry-air mixing ratios (mole fractions) of CO <sub>2</sub>
XCH <sub>4</sub>	Column-averaged dry-air mixing ratios (mole fractions) of CH <sub>4</sub>
L1	Level 1 satellite data product: geolocated radiance (spectra)
L2	Level 2 satellite-derived data product: Here: XCO <sub>2</sub> and XCH <sub>4</sub> information for each ground-pixel
L3	Level 3 satellite-derived data product: Here: Gridded XCO <sub>2</sub> and XCH <sub>4</sub> information, e.g., 5°x5°, monthly
L4	Level 4 satellite-derived data product: Here: Surface fluxes (emission and/or uptake) of CO <sub>2</sub> and CH <sub>4</sub>

## Scope of document

This document is an Algorithm Theoretical Basis Document (ATBD) for the Copernicus Climate Change Service (C3S, <https://climate.copernicus.eu/>) greenhouse gas (GHG) component as covered by project C3S\_312b\_Lot2.

Within this project satellite-derived atmospheric carbon dioxide (CO<sub>2</sub>) and methane (CH<sub>4</sub>) Essential Climate Variable (ECV) data products are generated and delivered to ECMWF for inclusion into the Copernicus Climate Data Store (CDS) from which users can access these data products and the corresponding documentation.

The satellite-derived GHG data products are:

- Column-averaged dry-air mixing ratios (mole fractions) of CO<sub>2</sub> and CH<sub>4</sub>, denoted XCO<sub>2</sub> (in parts per million, ppm) and XCH<sub>4</sub> (in parts per billion, ppb), respectively.
- Mid/upper tropospheric mixing ratios of CO<sub>2</sub> (in ppm) and CH<sub>4</sub> (in ppb).

This document describes the algorithms to generate the C3S products XCO<sub>2</sub>\_EMMA, XCH<sub>4</sub>\_EMMA, XCO<sub>2</sub>\_OBS4MIPS and XCH<sub>4</sub>\_OBS4MIPS.

These products are merged multi-sensor XCO<sub>2</sub> and XCH<sub>4</sub> Level 2 and Level 3 products generated using algorithms developed at University of Bremen, Germany.

For an overview of these merged Level 2 data products XCO<sub>2</sub>\_EMMA and XCH<sub>4</sub>\_EMMA and of these merged Level 3 data products XCO<sub>2</sub>\_OBS4MIPS and XCH<sub>4</sub>\_OBS4MIPS see also *Reuter et al., 2019*.

## Executive summary

This ATBD describes the algorithm theoretical basis for EMMA v4.1 CO<sub>2</sub> and EMMA v4.1 CH<sub>4</sub>. Originally, the EMMA algorithm (v1.3) was described in detail using the example of CO<sub>2</sub> in the publication of *Reuter et al. (2013)* and their publication is the blueprint for this ATBD.

For a long time, climate modelers have used ensemble approaches to calculate the ensemble median and to estimate uncertainties of climate projections where no ground-truth is known. Following this idea, the ensemble median algorithm EMMA brings together level 2 data of several SCIAMACHY, GOSAT, and OCO-2 XCO<sub>2</sub> and XCH<sub>4</sub> retrieval products independently developed by NASA, NIES, SRON, University of Leicester, and the University of Bremen. EMMA determines in 10°x10° degree grid boxes monthly averages and selects the level 2 data of the median algorithm. Thresholds depending on potential information content prevent from over-weighting individual algorithms with a considerably larger amount of data.

The EMMA database consists of individual level 2 soundings retrieved by algorithms which can change from grid box to grid box and month to month. Therefore, it can be used in the same manner as any other XCO<sub>2</sub> or XCH<sub>4</sub> satellite retrieval, i.e., the EMMA database includes all information needed for inverse modeling (geo-location, time, XCO<sub>2</sub> or XCH<sub>4</sub>, averaging kernels, etc.). Additionally, it includes the inter-algorithm spread which informs about potential regional or temporal systematic uncertainties.

Obs4MIPs (Observations for Model Inter-comparisons Project) is an activity to make observational products more accessible especially for climate model inter-comparisons. Based on EMMA's XCO<sub>2</sub> and XCH<sub>4</sub> L2 data bases, the XCO<sub>2</sub>\_OBS4MIPS and XCH<sub>4</sub>\_OBS4MIPS data products are generated by spatial (5°x5°) and temporal (monthly) gridding. The output is stored in the Obs4MIPs NCDF format, which is described on the Obs4MIPs website: <https://www.earthsystemcog.org/projects/obs4mips>.

## 1. Data product overview

Our current knowledge about the sources and sinks of atmospheric CO<sub>2</sub> and CH<sub>4</sub> is limited by the sparseness of highly accurate and precise measurements of these gases (e.g., *Stephens et al., 2007*). Due to their global coverage and sensitivity down to the surface, satellite based XCO<sub>2</sub> and XCH<sub>4</sub> (column-average dry-air mole fraction of atmospheric CO<sub>2</sub> and CH<sub>4</sub>) retrievals in the near infrared are promising candidates to reduce existing uncertainties if accurate and precise enough (e.g., *Rayner and O'Brien, 2001; Houweling et al., 2004; Miller et al., 2007; Chevallier et al., 2007*).

At present, several independently developed XCO<sub>2</sub> and/or XCH<sub>4</sub> retrieval algorithms exist for SCIAMACHY (SCanning Imaging Absorption spectroMeter of Atmospheric CHartography; *Burrows et al., 1995; Bovensmann et al., 1999*), GOSAT (Greenhouse gases Observing SATellite; *Yokota et al., 2004*), and OCO-2 (Orbiting Carbon Observatory-2; *Crisp et al., 2017*); see **Table 2** and **Table 3** for those used for EMMA v4.1 CO<sub>2</sub> and EMMA v4.1 CH<sub>4</sub>, respectively.

All retrieval teams find encouraging validation results when comparing with TCCON (total carbon column observing network, *Wunch et al., 2011*) ground based FTS (Fourier transform spectrometer) measurements (see references in the next section). This goes along with a good inter-algorithm agreement at TCCON sites and with the results of our unified validation study having station-to-station biases (i.e., the standard deviation of the biases at different sites) usually below 0.6ppm and 5.0ppb and single measurement precisions usually below 2.0ppm and 15ppb for XCO<sub>2</sub> and XCH<sub>4</sub>, respectively (**Figure 1, Figure 2, Table 4, Table 5**).

However, the inter-algorithm agreement often reduces remote from validation sites due to differing large scale bias patterns (see **Sec. 3.1**). Such biases can be a critical issue for surface flux inversions and the user requirements are demanding; as an example, *Miller et al. (2007)* and *Chevallier et al. (2007)* found that regional biases of a few tenths of a ppm can already hamper surface flux inversions. This indicates that assessing an algorithm's quality should not be based on comparisons against current TCCON stations only. Obviously, large regions of the world possess more "complicated" retrieval conditions without the availability of ground truth measurements which could be used to judge the algorithms' performance.

Diverging model results are common to many scientific disciplines (e.g., *Araujo and New, 2007; Rötter et al., 2011*) and much attention and effort is devoted to this topic on the subject of weather and climate modeling. Here, the divergence of the model results arises not only from structural differences of the different models, but also from the nonlinearity of the model equations, leading to differing results of one single model when performing multiple realizations with slightly differing initial conditions (*Hagedorn et al., 2005; Tebaldi and Knutti, 2007*).

Especially in the case of weather forecasting or climate projections, where no ground truth is available for the verification of the forecasts and projections, it is impossible to identify the "best" model and the "perfect" initial conditions. For long-term climate projections, this problem is impaired by the unknown future greenhouse forcing.

**Table 2:** Main retrieval characteristics of EMMA v4.1 CO<sub>2</sub> input XCO<sub>2</sub> data products: algorithm name and version, satellite instrument, spectral bands, inversion technique (OE = optimal estimation, TP = Tikhonov–Phillips regularization, LS = least squares), consideration of scattering (FP = full physics, PR = light path proxy, xEP20 = x extinction profiles with 20 layers (two aerosol types, water and ice cloud), ISL = isotropic scattering layer, TAU = scattering optical depth, SLH = scattering layer height, ANG = Angstrom exponent, CWP = cloud water path, CTH = cloud top height, AOD = aerosol optical depth, APNC = aerosol particle number concentration, ASP = aerosol size parameter, AH = aerosol height), main cloud filter (MERIS = medium resolution imaging spectrometer, CAI = cloud and aerosol imager of GOSAT, PMD = polarization measurement device of SCIAMACHY).

PPDF-S v02.xx	7531	14.40 (5.11)	6.64
EMMA v4.1 CH <sub>4</sub>	21931	13.69 (13.38)	3.66

This conceptual problem is dealt with by using multi-model, multi-realization, multi-emission-scenario ensembles of simulations, which ideally span the entire range of possible model outcomes and, thus, can be used to estimate the uncertainties of the forecast or projection.

However, interpreting the ensemble's spread as uncertainty is not the only possible application: some studies indicate that the ensemble mean, weighted mean, or median can outperform each individual model under appropriate conditions (e.g., *Kharin and Zwiers, 2002; Vautard et al., 2009*).

Here, we seize this idea and introduce the ensemble median algorithm EMMA which uses data from the retrieval algorithms listed in **Table 2** and **Table 3** and within the next section. EMMA generates a database of individual level 2 retrievals and takes advantage of the variety of different retrieval algorithms and their independent developments.

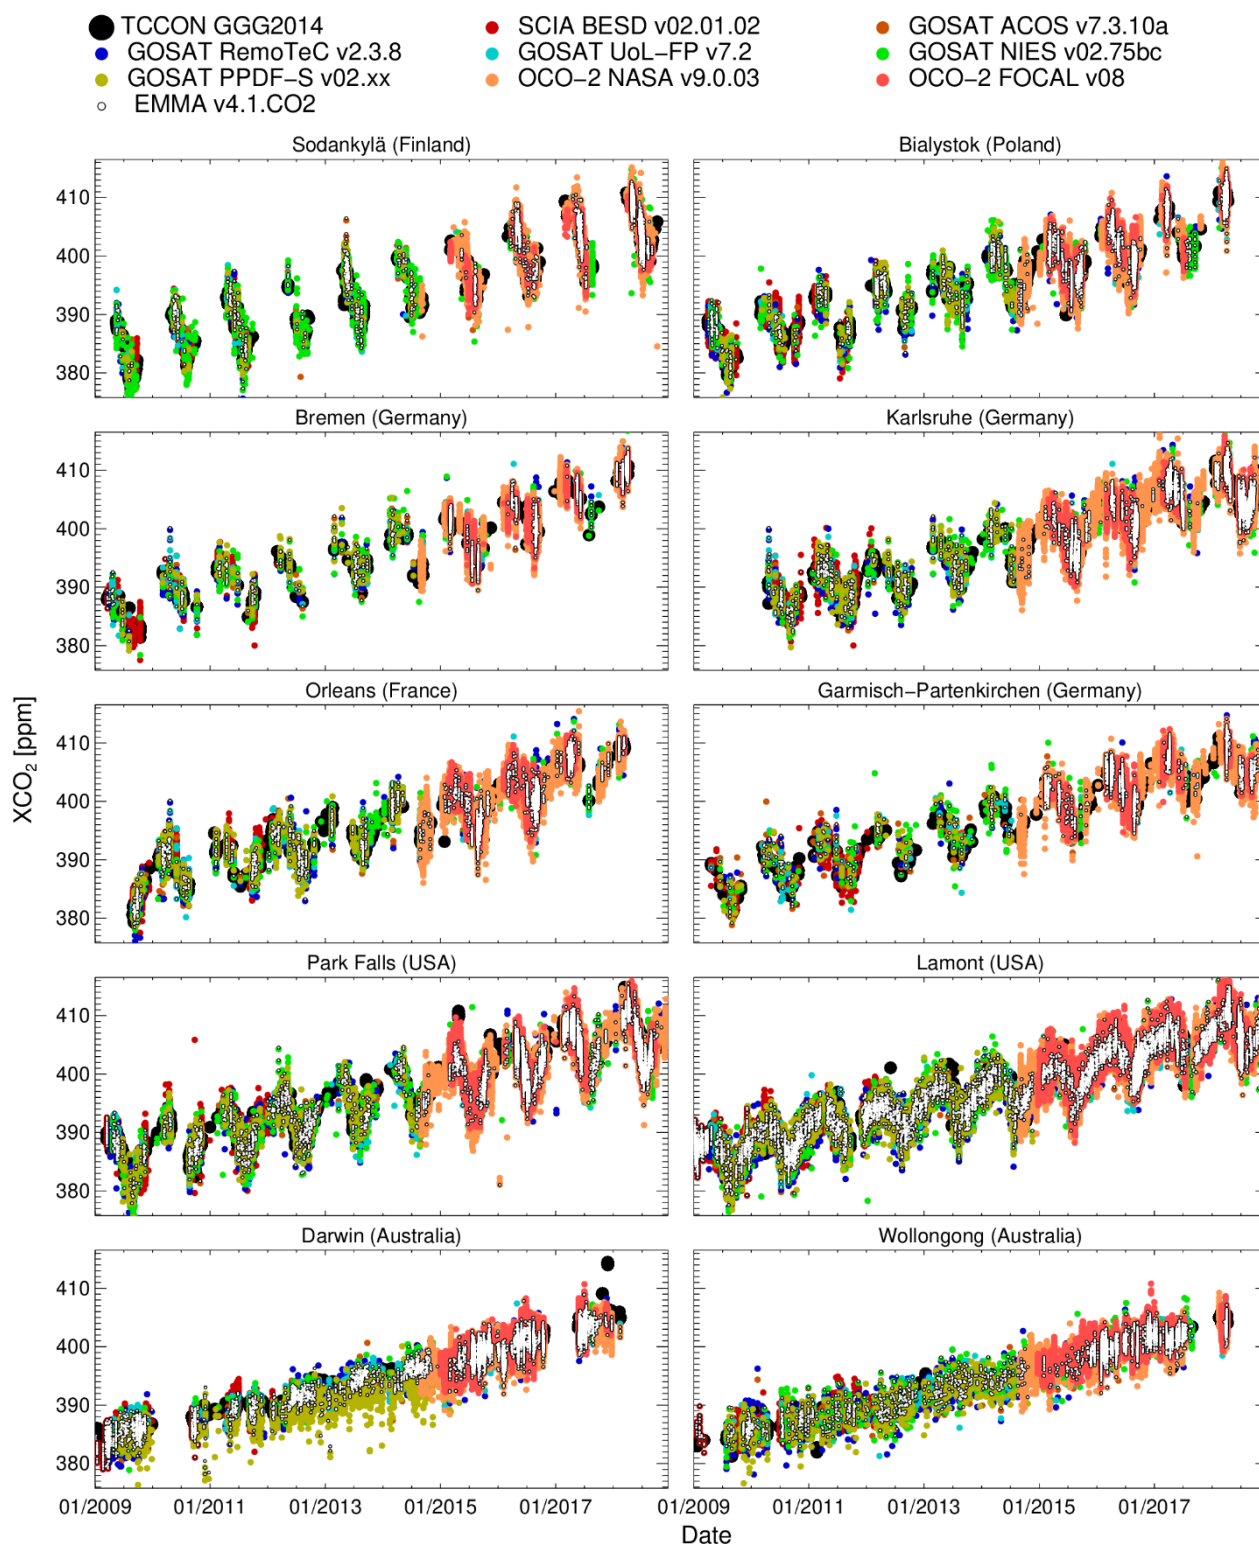

For each month and each  $10^{\circ} \times 10^{\circ}$  grid box, one algorithm is chosen to supply level 2 retrievals for the database. The algorithm is chosen on the basis that its grid box mean is the median amongst the available algorithms. This allows the reduction of occasional outliers and sometimes unrealistic bias patterns, which may be found in each individual retrieval algorithm and which may hamper surface flux inversions. EMMA relies on the assumption that it is unlikely that the majority of algorithms produce outliers in the same direction because only in this case the median is a bad choice.

Smoothing of real atmospheric variability, as it could happen when dealing with climate model ensembles, cannot be expected for EMMA because all ensemble members ( $\text{XCO}_2$  or  $\text{XCH}_4$  retrieval algorithms) represent the same (real) atmospheric  $\text{XCO}_2$  or  $\text{XCH}_4$  conditions and deviations from the real values are always due to retrieval errors (sampling issues are neglected in this context).

The EMMA database includes all information needed for inverse modeling (geo-location, time,  $\text{XCO}_2$  or  $\text{XCH}_4$ , averaging kernels, etc.). As it consists of individual  $\text{XCO}_2$  or  $\text{XCH}_4$  retrievals, it can be used in the same manner as any other  $\text{XCO}_2$  or  $\text{XCH}_4$  satellite retrieval. Additionally, the EMMA database includes the inter-algorithm spread which gives important information about regional and/or temporal systematic uncertainties.

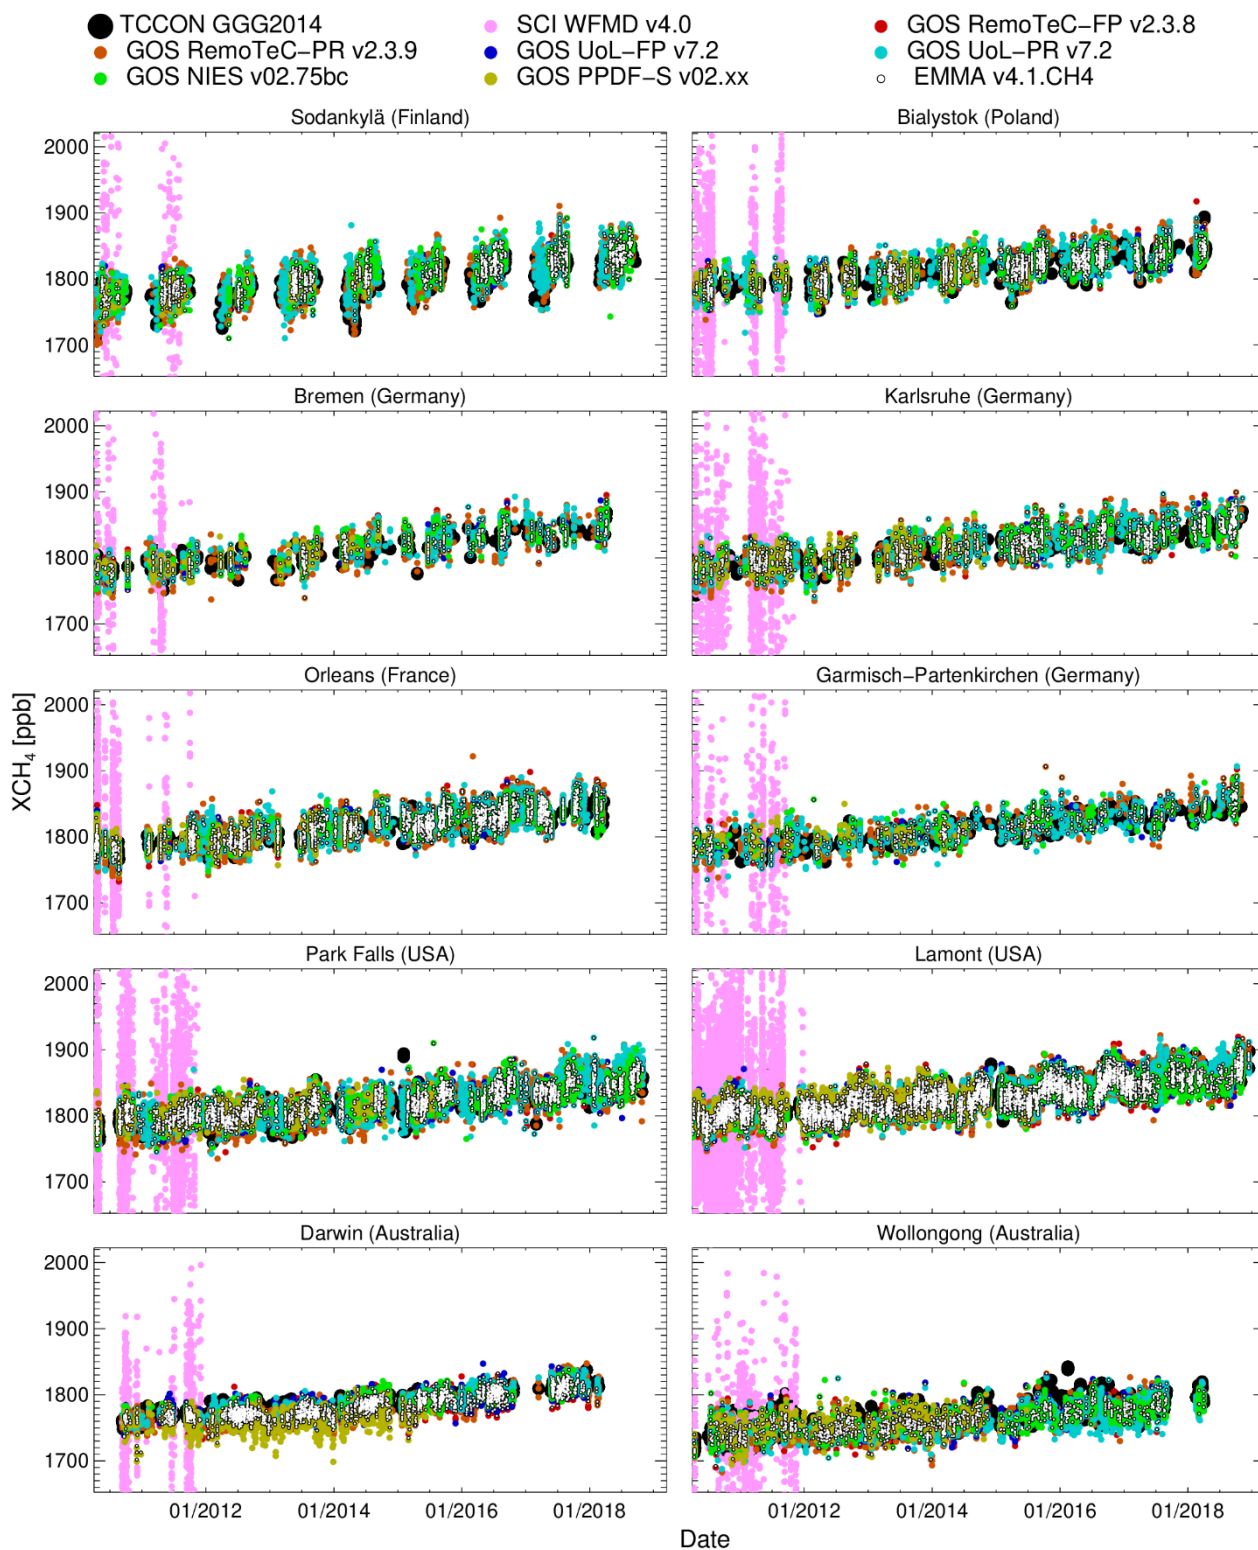

**Figure 1:** Validation of individual XCO<sub>2</sub> algorithms and EMMA v4.1 CO<sub>2</sub> with TCCON GGG2014.

**Figure 2:** Validation of individual XCH<sub>4</sub> algorithms and EMMA v4.1 CH<sub>4</sub> with TCCON GGG2014.

## 2. Input and auxiliary data

### 2.1. Satellite instrument

At present, several different XCO<sub>2</sub> and/or XCH<sub>4</sub> retrieval algorithms exist for SCIAMACHY, GOSAT, and OCO-2 which are under active development in order to meet the demanding user requirements, making them useful for surface flux inversions. Specifically, we here make use of SCIAMACHY BESD v02.01.02 (Reuter et al., 2016), GOSAT RemoTeC v2.3.8 (Detmers et al., 2017a), GOSAT ACOS v7.3.10a (O'Dell et al., 2012), GOSAT UoL-FP v7.2 (Boesch and Anand, 2017), GOSAT NIES v02.75bc (Yoshida et al., 2013), GOSAT NIES PPDF-S v02.xx (Bril et al., 2012), OCO-2 NASA v9.0.03 (Kiel et al., 2019), and OCO-2 FOCAL v08 (Reuter et al., 2017a,b) for XCO<sub>2</sub> and WFMD v4.0 (Schneising et al., 2016), RemoTeC-FP v2.3.8 (Detmers et al., 2017a), RemoTeC-PR v2.3.9 (Detmers et al., 2017b), UoL-FP v7.2 (Boesch and Anand, 2017), UoL-PR v7.2 (Boesch and Anand, 2017), NIES v02.75bc (Yoshida et al., 2011), and PPDF-S v02.xx (Bril et al., 2012) for XCH<sub>4</sub>.

The basic principle of all these algorithms is the same: (i) A satellite instrument measures backscattered solar radiation in near-infrared O<sub>2</sub> and CO<sub>2</sub> or CH<sub>4</sub> absorption bands. (ii) A radiative transfer plus instrument model (forward model) is utilized to simulate the satellite measurement for a set of known parameters (parameter vector) and unknown parameters (state vector). (iii) An inversion method tries to find that state vector which results in best agreement of simulated and measured radiances. (iv) The retrieved state vector is assumed to represent the true (or most likely) atmospheric state.

However, when going into more detail, the algorithms have distinct conceptual differences: the algorithms are optimized for different instruments (SCIAMACHY, GOSAT, or OCO-2). They are based on different absorption bands, use different inversion methods (optimal estimation, Tikhonov-Phillips, least squares), and are based on different physical assumptions on the radiative transfer in scattering atmospheres. In order to give two examples, so-called full physics algorithms explicitly account for (multiple) scattering at molecules, aerosols, and/or clouds by having state vector elements such as cloud water path, cloud top height, and aerosol optical thickness; the light path proxy method assumes that photon path lengths are modified similarly in the CO<sub>2</sub> and O<sub>2</sub> or CH<sub>4</sub> absorption bands, and that scattering related effects cancel out when dividing the retrieved CO<sub>2</sub> and O<sub>2</sub> or CH<sub>4</sub> columns when building XCO<sub>2</sub> or XCH<sub>4</sub>. Additionally, the algorithms use different pre- and post-processing filters (e.g., cloud detection from O<sub>2</sub>-A band or from a cloud and aerosol imager).

The main properties of the used retrieval algorithms are summarized in **Table 2** and **Table 3**. This list does not claim to be exhaustive and there are other aspects which can also easily result in differences of some ppm (e.g., spectroscopy). Discussions of the specific strengths and weaknesses and many more points, where the individual algorithms differ, can be found in the cited literature.

## 2.2. Other

In order to account for different column averaging kernels, all retrieval results are adjusted to a common a priori, namely the latest update (2018) of the Simple Empirical CO<sub>2</sub> Model (SECM, see below) of *Reuter et al. (2012)* or the latest version (2018) of a model based CH<sub>4</sub> climatology adjusted for the annual growth called SC4C (see below).

SECM (*Reuter et al. (2012)*) is essentially an empirically found function with parameters optimized using a CO<sub>2</sub> model (here CT2017, see below). The SECM2018 model used here is an update of the SECM model described in Reuter et al., 2012. The main difference is that SECM2018 is using a recent version of NOAA's assimilation system CarbonTracker (*Peters et al., 2007*, with updates documented at <http://carbontracker.noaa.gov/>), namely CT2017.

SC4C refers to the "Simple CH<sub>4</sub> Climatological model" and we use the year 2018 update referred to as SC4C2018. The SC4C2018 model is similar as SECM2018 (see above) but for XCH<sub>4</sub>. It is a model-based CH<sub>4</sub> climatology adjusted for the annual growth rate (note that this model has also been used as climatological training and calibration data set as described in *Schneising et al., 2019*).

Scaling the reported uncertainties and validation is done with TCCON (total carbon column observing network, *Wunch et al., 2011*) GGG2014 as reference data set.

## 3. Algorithms

### 3.1. EMMA ensemble spread

Due to entirely different samplings (different satellites, different filtering strategies, etc.), any algorithm inter-comparison considering the majority of individual soundings (level 2) can only be based on aggregated data (level 3), in our case monthly averages on a  $10^{\circ} \times 10^{\circ}$  grid.

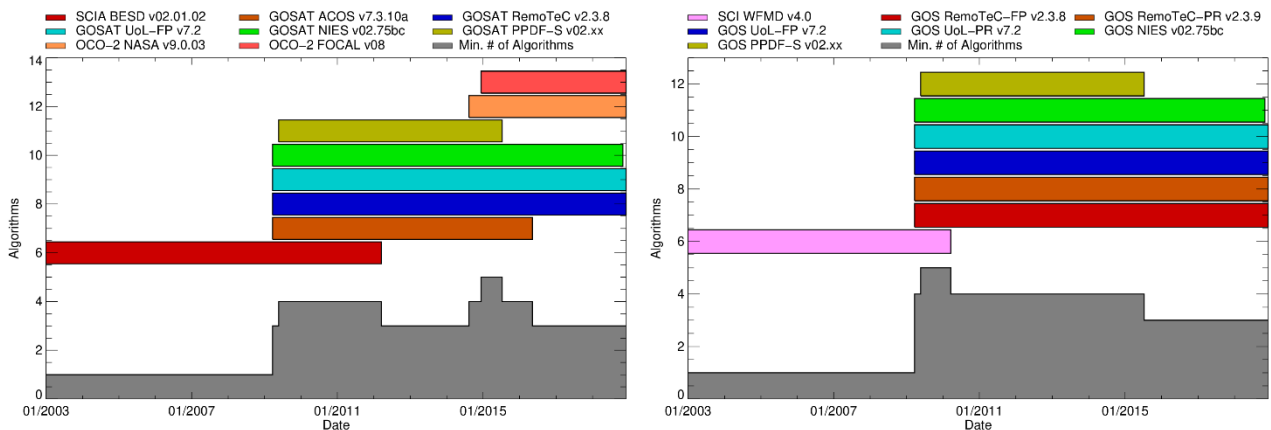

Before gridding, we apply the individual averaging kernels to adjust all retrieval results to a common a priori, namely the latest version (2018) of the Simple Empirical CO<sub>2</sub> Model (SECM) of *Reuter et al. (2012)* or the latest version (2018) of a model based CH<sub>4</sub> climatology adjusted for the annual growth called SC4C (see Sect. 2.2). We do this as proposed in the textbook of *Rodgers (2000)* and applied to XCO<sub>2</sub> by, for example, *Reuter et al. (2011)*. SECM and SC4C reproduce large-scale features such as the year-to-year increase, the north/south gradient, and the seasonal cycle. However, SECM and SC4C are only empirically extrapolating from past modeled CO<sub>2</sub> and CH<sub>4</sub> fields. New or changing phenomena cannot be within SECM or SC4C, and it should also be mentioned that the adjustments are mostly minor, especially for CO<sub>2</sub> with typically a few tenths of a ppm.

For consistency, we remove the overall global bias of each retrieval with SECM or SC4C as reference. In order to get statistically robust results, we only use those grid boxes with more than five soundings and for which the standard error of the mean is estimated to be less than 1ppm and 12ppb for XCO<sub>2</sub> and XCH<sub>4</sub>, respectively. This takes the individual retrieval precisions into account so that the minimum number of soundings needed to build the average of a grid box can vary from retrieval to retrieval and grid box to grid box. Additionally, only grid boxes with a maximum number of overlapping algorithms (see **Figure 3**) are considered for the global bias adjustment. Beforehand, the reported retrieval precision is scaled to match (on average) the precision given in **Table 4** and **Table 5** obtained from a unified validation with TCCON data (**Figure 1** and **Figure 2**). **Figure 4** shows the influence of the global bias correction.

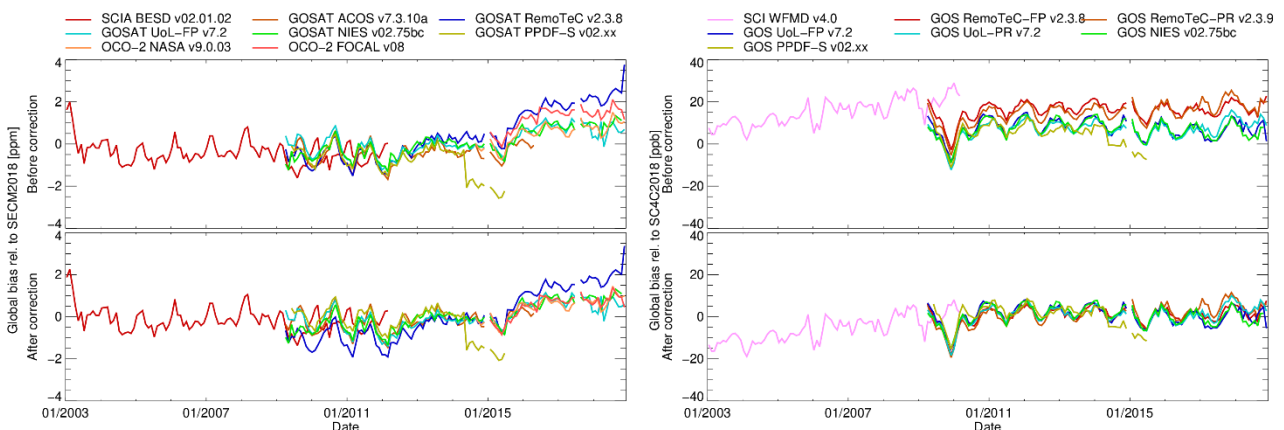

**Figure 3:** EMMA v4.1 input data availability (colored bars) and minimum number of used algorithms (gray) for median calculation for CO<sub>2</sub> (left) and CH<sub>4</sub> (right).

**Figure 4:** Global monthly average bias for XCO<sub>2</sub> (left) and XCH<sub>4</sub> (right) in common grid boxes relative to SECM (XCO<sub>2</sub>) and SC4C (XCH<sub>4</sub>) before (top) and after (bottom) global bias correction.

**Figure 5** and **Figure 6** show at the example of April 2015 the calculated monthly XCO<sub>2</sub> or XCH<sub>4</sub> averages, respectively. First of all, one can see many large scale similarities such as the north/south gradient. However, one can also find more or less obvious outliers in the order of a percent for several algorithms. Often the observed systematic deviations (of level 3 data) are larger than expected from instrumental noise, i.e., they are dominated by specific algorithm effects. As level 3 grid boxes are always calculated from several individual level 2 soundings (ideally) sampled all over the grid box, we expect that sampling and representation errors are lower than the observed deviations. Therefore, these errors are not discussed further in this context.

Due to independent algorithm developments, different physical approaches and assumptions, different pre- and post-processing filters, and due to the different instruments, we expect relatively independent bias patterns. This is supported by **Figure 5** and **Figure 6**, which show (uncorrelated)

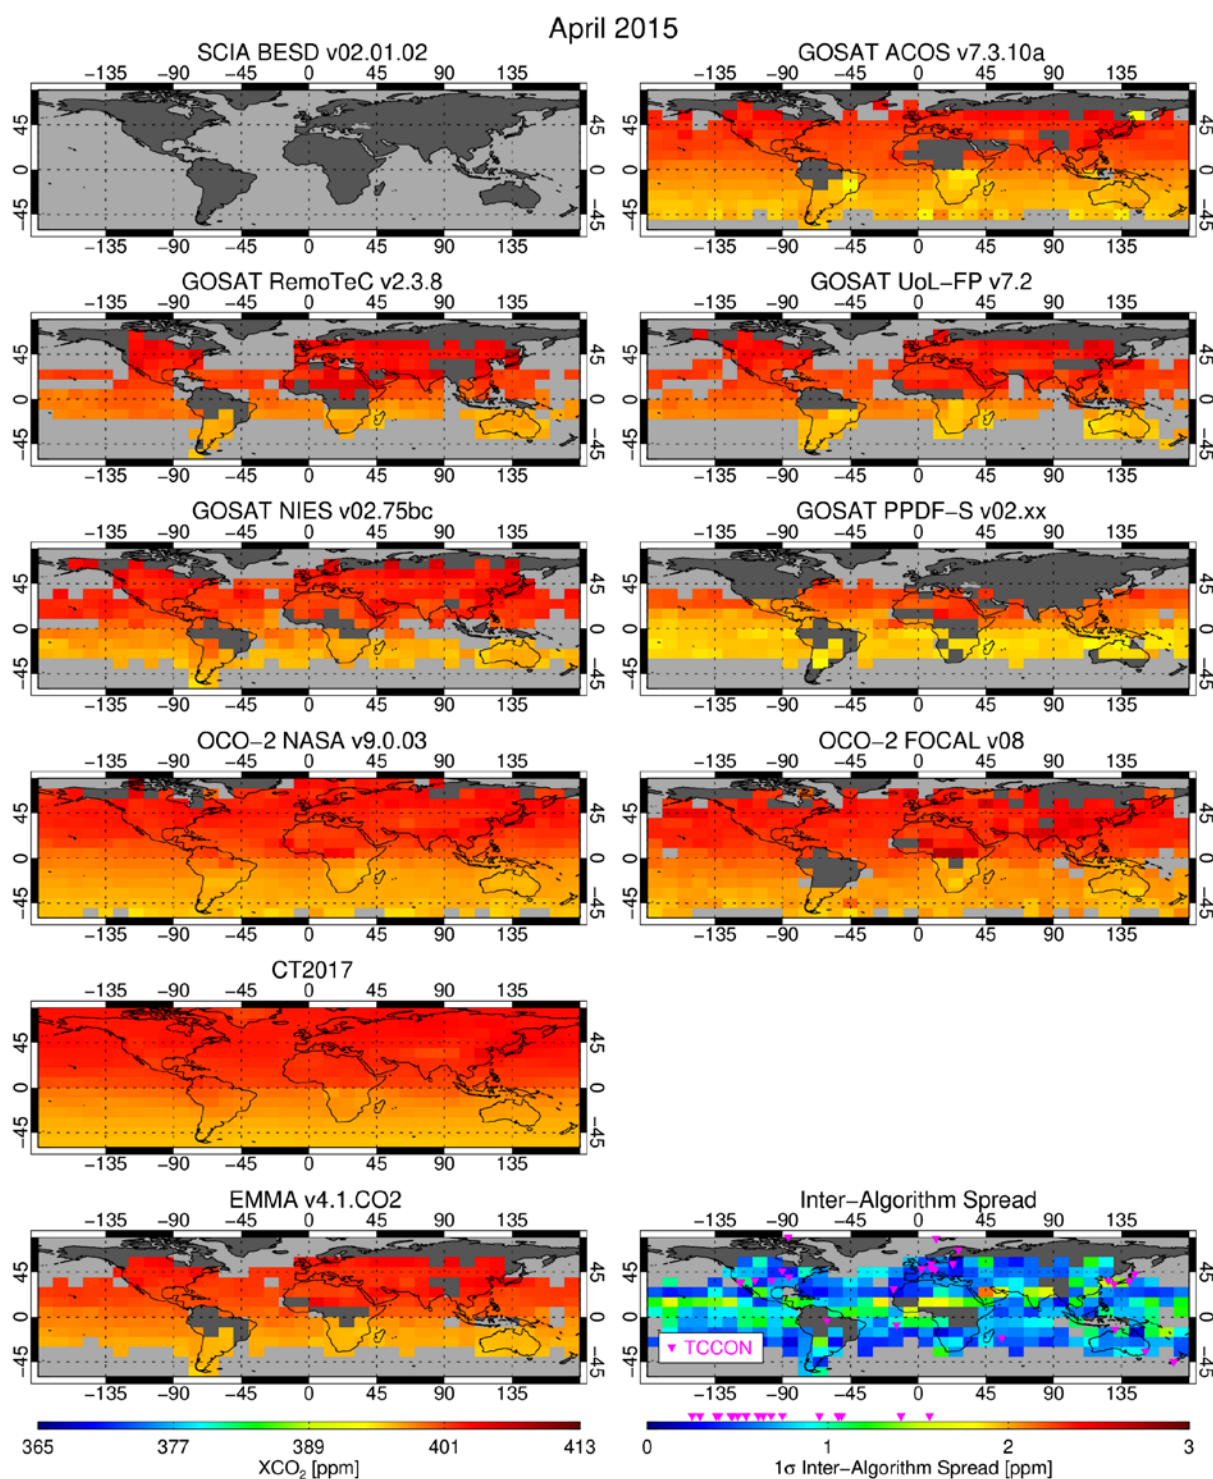

obvious outliers in various regions, i.e., it seems unlikely that all algorithms produce the same bias within one grid box. This implies that similar averages within one grid box can give us more confidence in the individual retrievals within this grid box. On the other hand, large inter-algorithm spreads indicate regions with more difficult and uncertain retrieval conditions. Therefore, we interpret the ensemble spread, i.e., the standard deviation, as uncertainty due to regional retrieval biases. An example is given in **Figure 7** showing larger inter-algorithm spreads for  $\text{XCO}_2$  and  $\text{XCH}_4$  in the tropics and in East Asia (mostly remote from TCCON sites). This pattern is temporally more or less stable, i.e., similar also in other months.

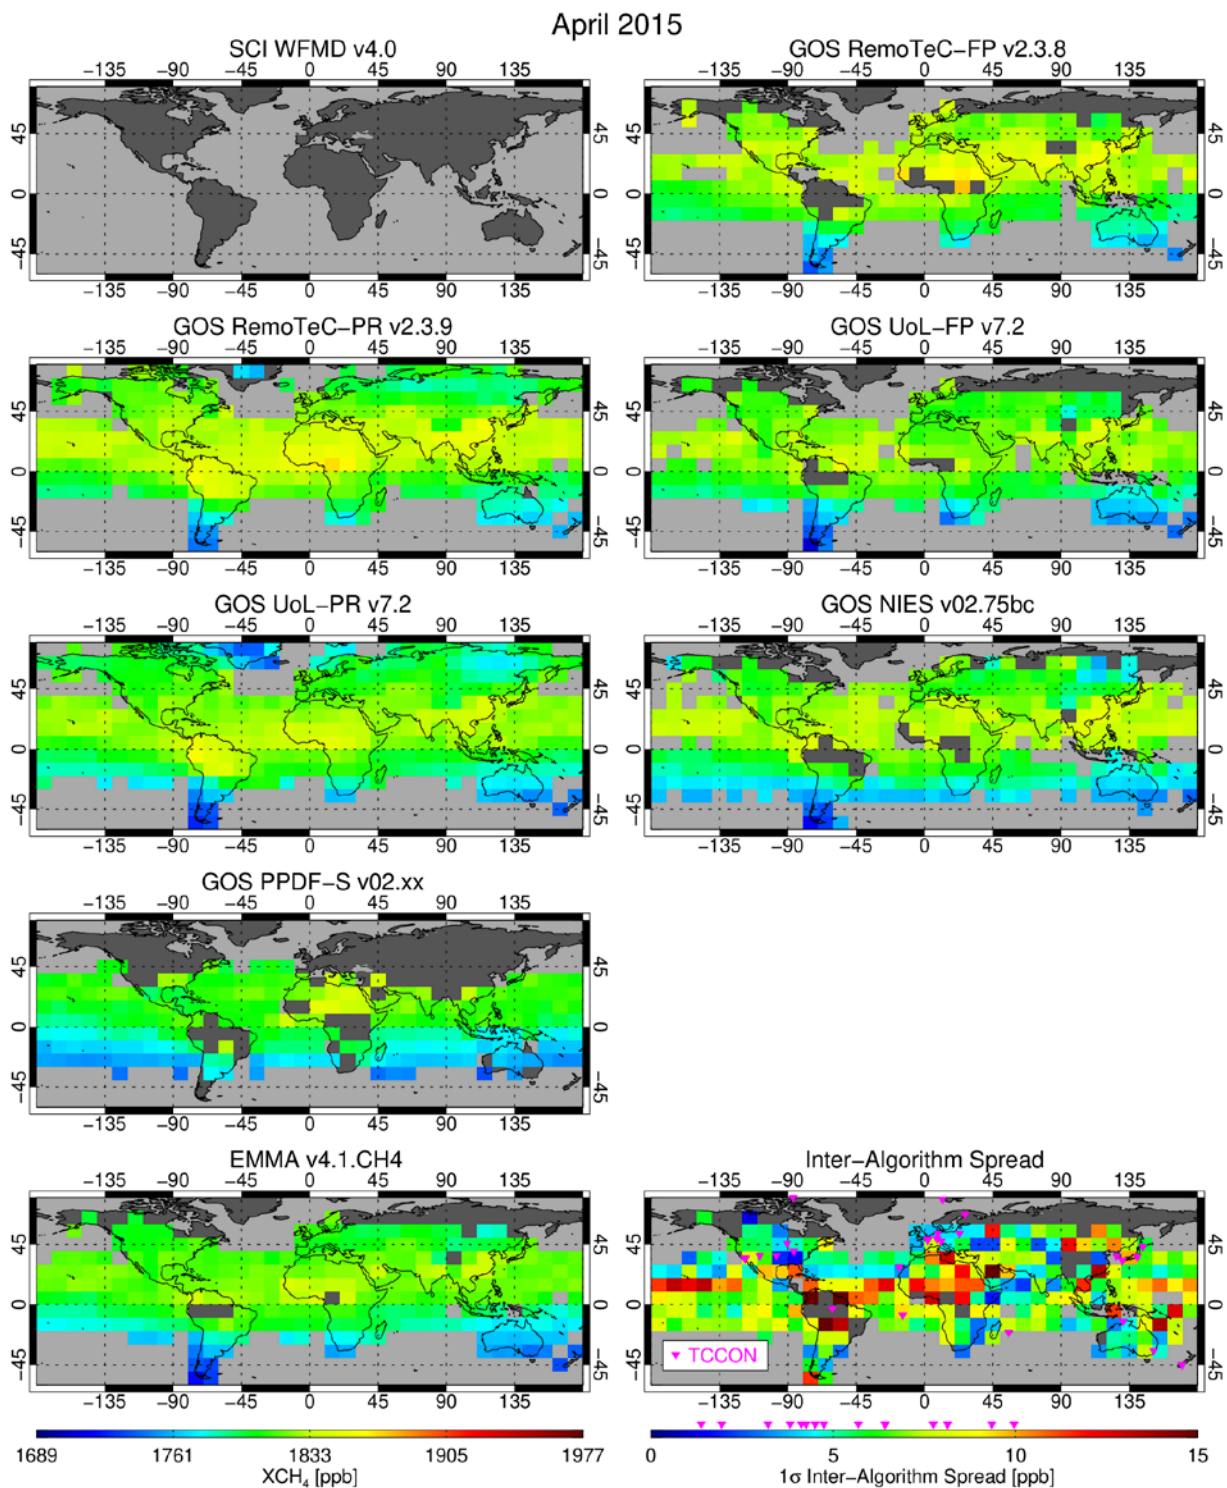

**Figure 5:** Monthly gridded XCO<sub>2</sub> averages and inter-algorithm spread at the example of April 2015 for EMMA v4.1 CO<sub>2</sub>.

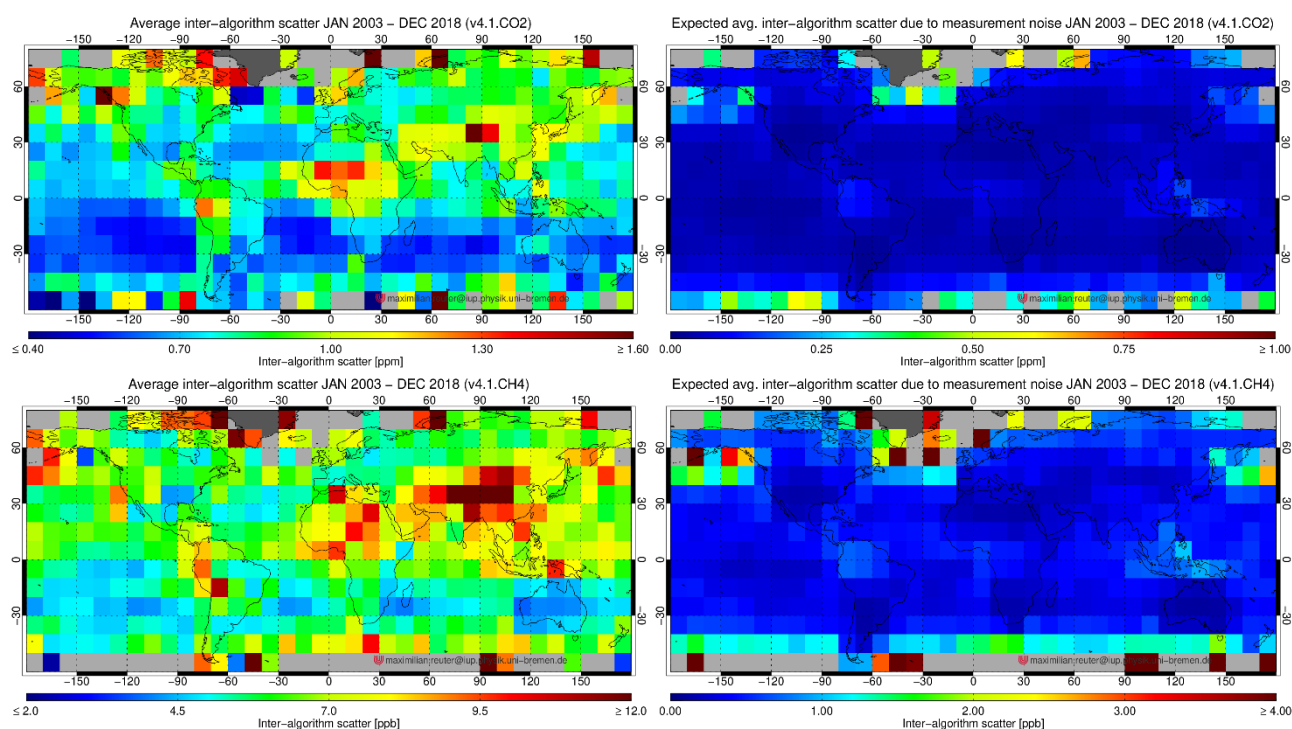

**Figure 6:** Monthly gridded XCH<sub>4</sub> averages and inter-algorithm spread at the example of April 2015 for EMMA v4.1 CH<sub>4</sub>.

**Figure 7:** Average inter-algorithm spread (01/2003 – 12/2018) (**left**) and expected average inter-algorithm spread due to measurement noise (**right**) for EMMA v4.1 CO<sub>2</sub> (**top**) and EMMA v4.1 CH<sub>4</sub> (**bottom**).

### 3.2. EMMA ensemble median

As described in the previous section, XCO<sub>2</sub> or XCH<sub>4</sub> averages (one for each algorithm) are calculated within each grid box. However, now, we are aiming to use the ensemble not only to assess regional and temporal uncertainties but also to create a data set which is potentially less influenced by regional or temporal biases. This could be achieved, for example, by building the average, a weighted average, or the median in each grid box.

In this context, the median has some advantages: outliers are assumed to be seldom and there is a high chance that a grid box includes no or only one outlying algorithm. Therefore, cancellation of errors cannot be expected by calculating the average. The median is much less sensitive to such individual outliers. Additionally, the median calculates no new quantity from the individuals of an ensemble, it is rather a procedure to select one specific ensemble member.

This allows us to trace back from level 3 averages to individual level 2 soundings. Essentially, there are five possible scenarios for median calculation within one grid box: (i) All algorithms perform well and scatter slightly around the true XCO<sub>2</sub> or XCH<sub>4</sub> value. In this case the median will help to reduce scatter. (ii) The minority of algorithms produce outliers so that the median is influenced only marginally. (iii) The majority of algorithms produce outliers in different directions. Here, it is still likely that the median falls on a well performing algorithm in the “middle”. (iv) The majority of algorithms produce outliers in the same direction. This is the only case where the median is a bad

choice, because it would select an outlier and ignore a well performing algorithm. As discussed in the previous section, we assume that the algorithms within one grid box are often realistic with uncorrelated occasional outliers, which makes this case unlikely to happen often. (v) If all algorithms are outlying, the median is not better or worse than selecting any other ensemble member.

We calculate the median only in grid boxes where reliable average XCO<sub>2</sub> or XCH<sub>4</sub> values can be computed for at least as many algorithms as specified in **Figure 3** (gray area). In case of an even number of values, we define the median as that value being closer to the mean. We then trace back to the individual level 2 data, which were used to calculate that average being the median.

Together, with all information needed for inverse modeling (geo-location, time, averaging kernels, etc.), these soundings are stored in the EMMA database.

Some algorithms may provide considerably larger amounts of level 2 data (e.g., the NASA or FOCAL OCO-2 algorithm) than other algorithms. In order to prevent over-weighting these algorithms, we limit the maximum number of data points (per grid box). Therefore, we calculate the standard error of the mean of each successfully determined average. The idea behind this is that the lower the standard error of the mean, the larger the potential constraint on an inverse model becomes. If the standard error of the mean of the selected algorithm in a grid box is lower than  $1/\sqrt{2}$  times the 25<sup>th</sup> percentile of all algorithms, the data points are randomly thinned accordingly. In this way, the number of data points can still be rather different but the potential constraint on an inverse model becomes similar.

### 3.3. OBS4MIPS

The L3 data products XCO<sub>2</sub>\_OBS4MIPS and XCH<sub>4</sub>\_OBS4MIPS are generated by spatial (5°x5°) and temporal (monthly) gridding of the corresponding EMMA L2 data bases. The gridding bases on arithmetic unweighted averaging of all soundings falling in a grid box. For each grid box, we compute the standard error of the mean by

$$\bar{\sigma} = \frac{1}{n} \sqrt{\sum \sigma_i^2}$$

where  $n$  is the number of soundings within the grid box and  $\sigma_i$  the (corrected) reported stochastic uncertainties of the soundings. In order to reduce noise within the level 3 product, we filter out grid boxes with  $n \leq 1$  and  $\bar{\sigma} > 1.6\text{ppm}$  for XCO<sub>2</sub> or  $\bar{\sigma} > 12\text{ppb}$  for XCH<sub>4</sub>, respectively.

Beside XCO<sub>2</sub> or XCH<sub>4</sub>, the final level 3 product also includes the number of soundings used for averaging, the average column averaging kernel, the average a priori profile, the standard deviation of the averaged XCO<sub>2</sub> or XCH<sub>4</sub> values, and an estimate for the total uncertainty

$$\hat{\sigma} = \sqrt{\bar{\sigma}^2 + \sigma_s^2}.$$

Here,  $\sigma_s$  represents the inter-algorithm spread computed by EMMA averaged over the soundings within a grid box. For cases including only one algorithm,  $\sigma_s$  is replaced by quadratically adding spatial and seasonal accuracy determined from the TCCON validation (see D2, Table 2).

However, this is only the case during the SCIAMCHY-only period at the beginning of the time series (see **Figure 3**).

## 4. Output data

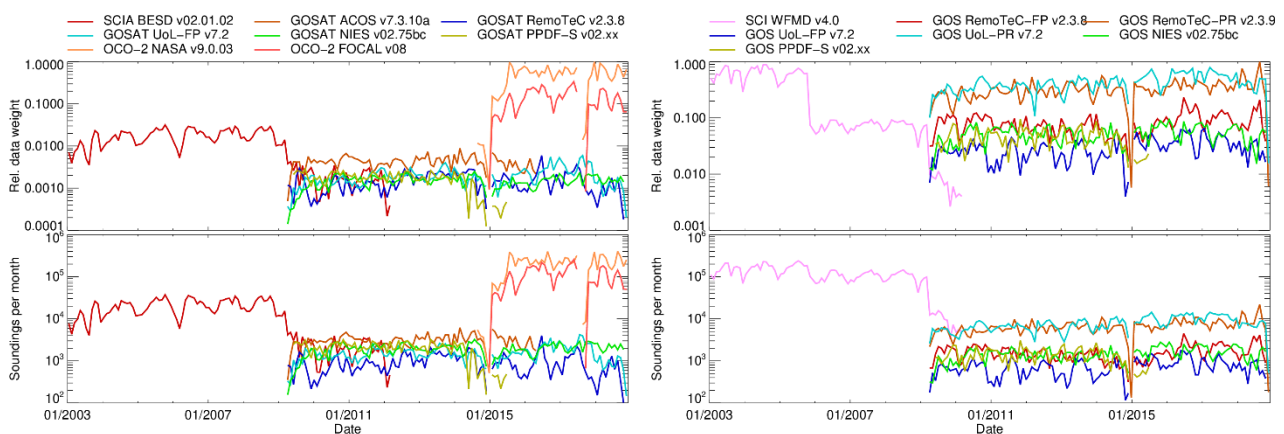

### 4.1. EMMA products

The EMMA database consists of individual level 2 soundings retrieved by algorithms which can change from grid box to grid box and month to month. Therefore, it can be used in the same manner as any other XCO<sub>2</sub> or XCH<sub>4</sub> satellite retrieval. **Figure 8** shows the relative data weight of each algorithm (defined as  $\sum 1/\sigma_i^2$  normalized to one) within the EMMA database per month. The EMMA database includes all information needed for inverse modeling (geo-location, time, XCO<sub>2</sub> or XCH<sub>4</sub>, averaging kernels, etc.). Additionally, it includes the inter-algorithm spread which informs about potential regional uncertainties.

At the example of April 2015, **Figure 9** shows the EMMA v4.1 XCO<sub>2</sub> or XCH<sub>4</sub> values as well as the corresponding selected median algorithm.

Note that the format of the main output data, which are the Level 2 data products, is described in the separate Product User Guide and Specification (PUGS) document.

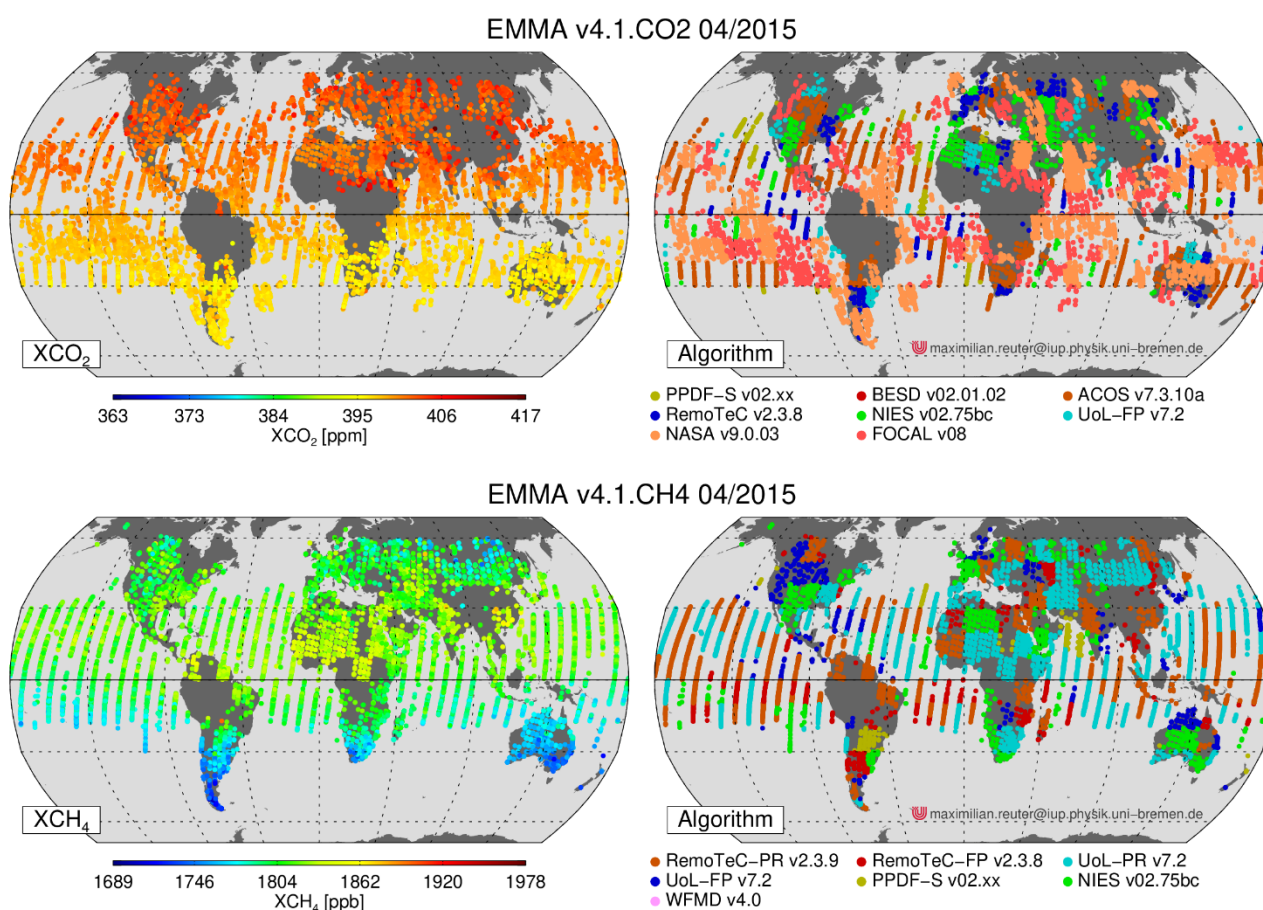

**Figure 8:** EMMA v4.1 normalized relative data weight proportional to  $\sum 1/\sigma_i^2$  (**top**) and number of soundings (**bottom**) per algorithm and month for CO<sub>2</sub> (**left**) and CH<sub>4</sub> (**right**).

**Figure 9:** EMMA L2 XCO<sub>2</sub> and XCH<sub>4</sub> (**left**) and corresponding selected algorithm (**right**) for EMMA v4.1 CO<sub>2</sub> at the example of April 2015 (**top**) and EMMA v4.1 CH<sub>4</sub> at the example of April 2015 (**bottom**).

## 4.2. OBS4MIPS products

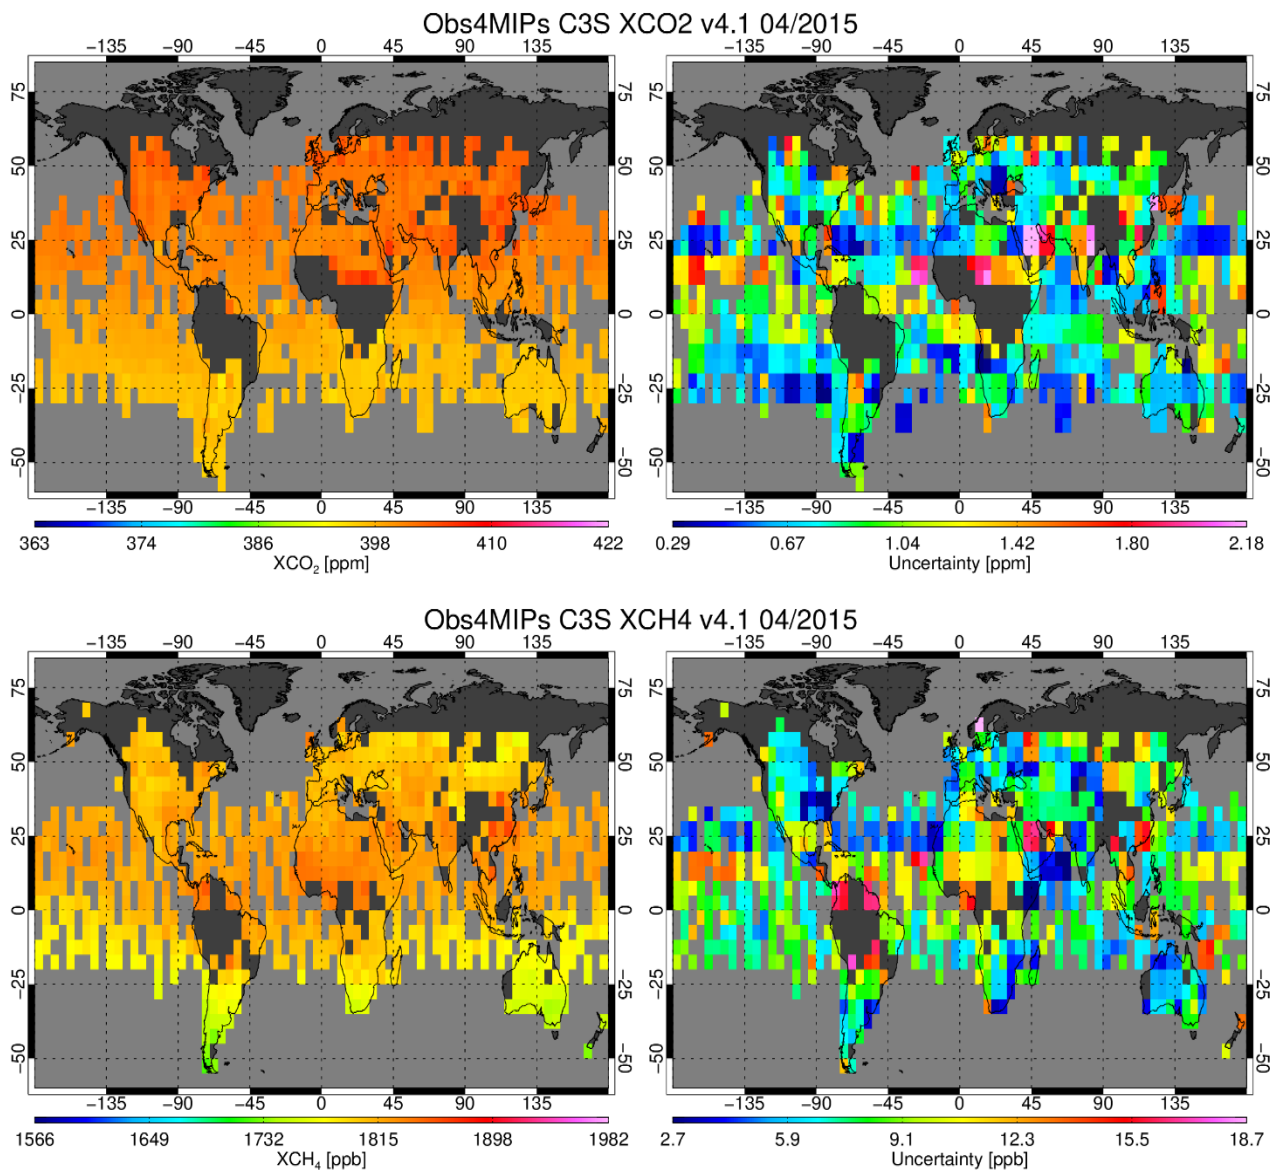

The XCO<sub>2</sub>\_OBS4MIPS and XCH<sub>4</sub>\_OBS4MIPS products consist of monthly, 5°x5° gridded level 3 XCO<sub>2</sub> or XCH<sub>4</sub> data computed from the corresponding EMMA databases. Additionally, the output files include gridded information about the number of averaged soundings, column averaging kernels, a priori profiles, standard deviation of XCO<sub>2</sub> or XCH<sub>4</sub>, and an estimate of the total uncertainty accounting for measurement noise plus potential spatial and/or temporal biases.

At the example of April 2015, **Figure 10** shows the OBS4MIPS XCO<sub>2</sub> or OBS4MIPS XCH<sub>4</sub> values as well as the corresponding total uncertainty.

Note that the format of the output data, which are the level 3 data products, is described in the separate Product User Guide and Specification (PUGS) document (D2).

**Figure 10: Top: XCO<sub>2</sub>\_OBS4MIPS XCO<sub>2</sub> for April 2015 (left) and its uncertainty computed from the retrieval noise and EMMA's inter-algorithm spread (right). Bottom: Same for XCH<sub>4</sub>\_OBS4MIPS.**
