# Overview

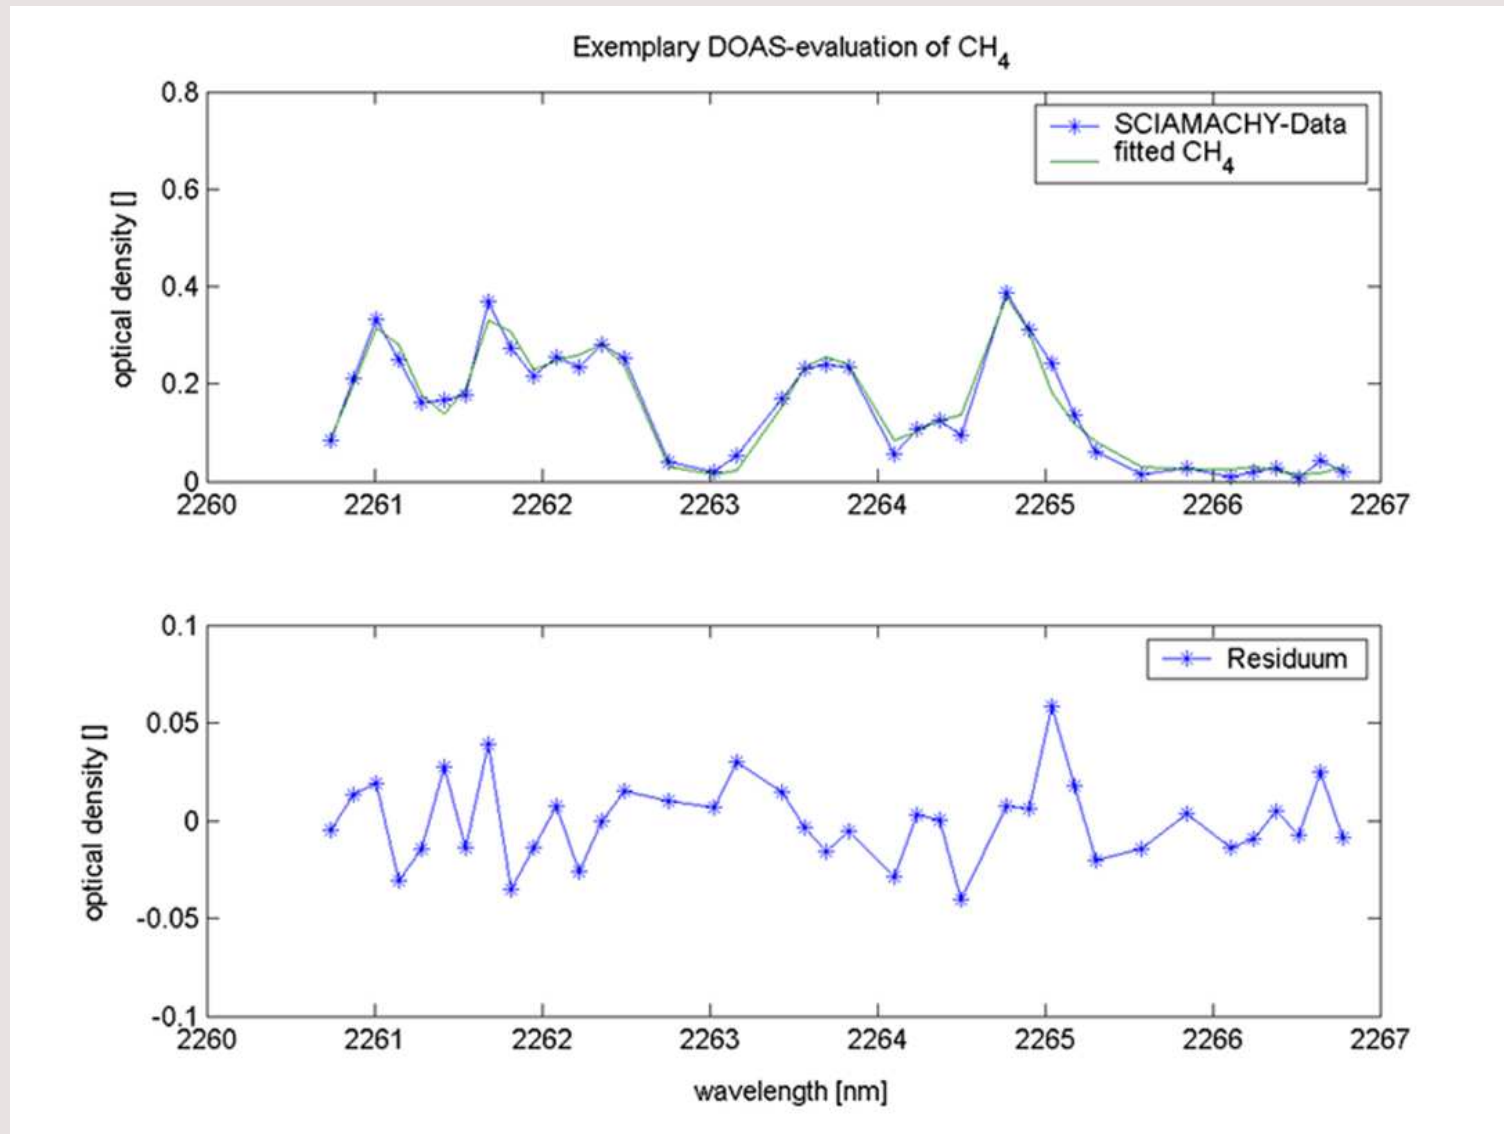

- Retrieval method
  - Retrieval problems
    - [1] Deviations using different wavelength regions
    - [2] Unexplainable spectral structures over the Mediterranean
    - [3] Reflectance deviations  $\text{PMD}_6$  and Channel 8
  - Future plans
-

# Retrieval method

# Retrieval problems [1]

- Retrieval depends on the radiance
  - Clouds, mountains etc. also affect the radiance (inducing artificial correlation between radiance & retrieval)
  - To avoid the artificial correlation CH<sub>4</sub> fits were performed using different spectral regions. The ratios of the VCD's are supposed to be independent on the radiance ratios
-

- Correlation indicates incorrect dark current correction
  - Correlation is different using other spectral regions or orbits (dark current not quantifiable)
- à This method will only be used for quality control
-

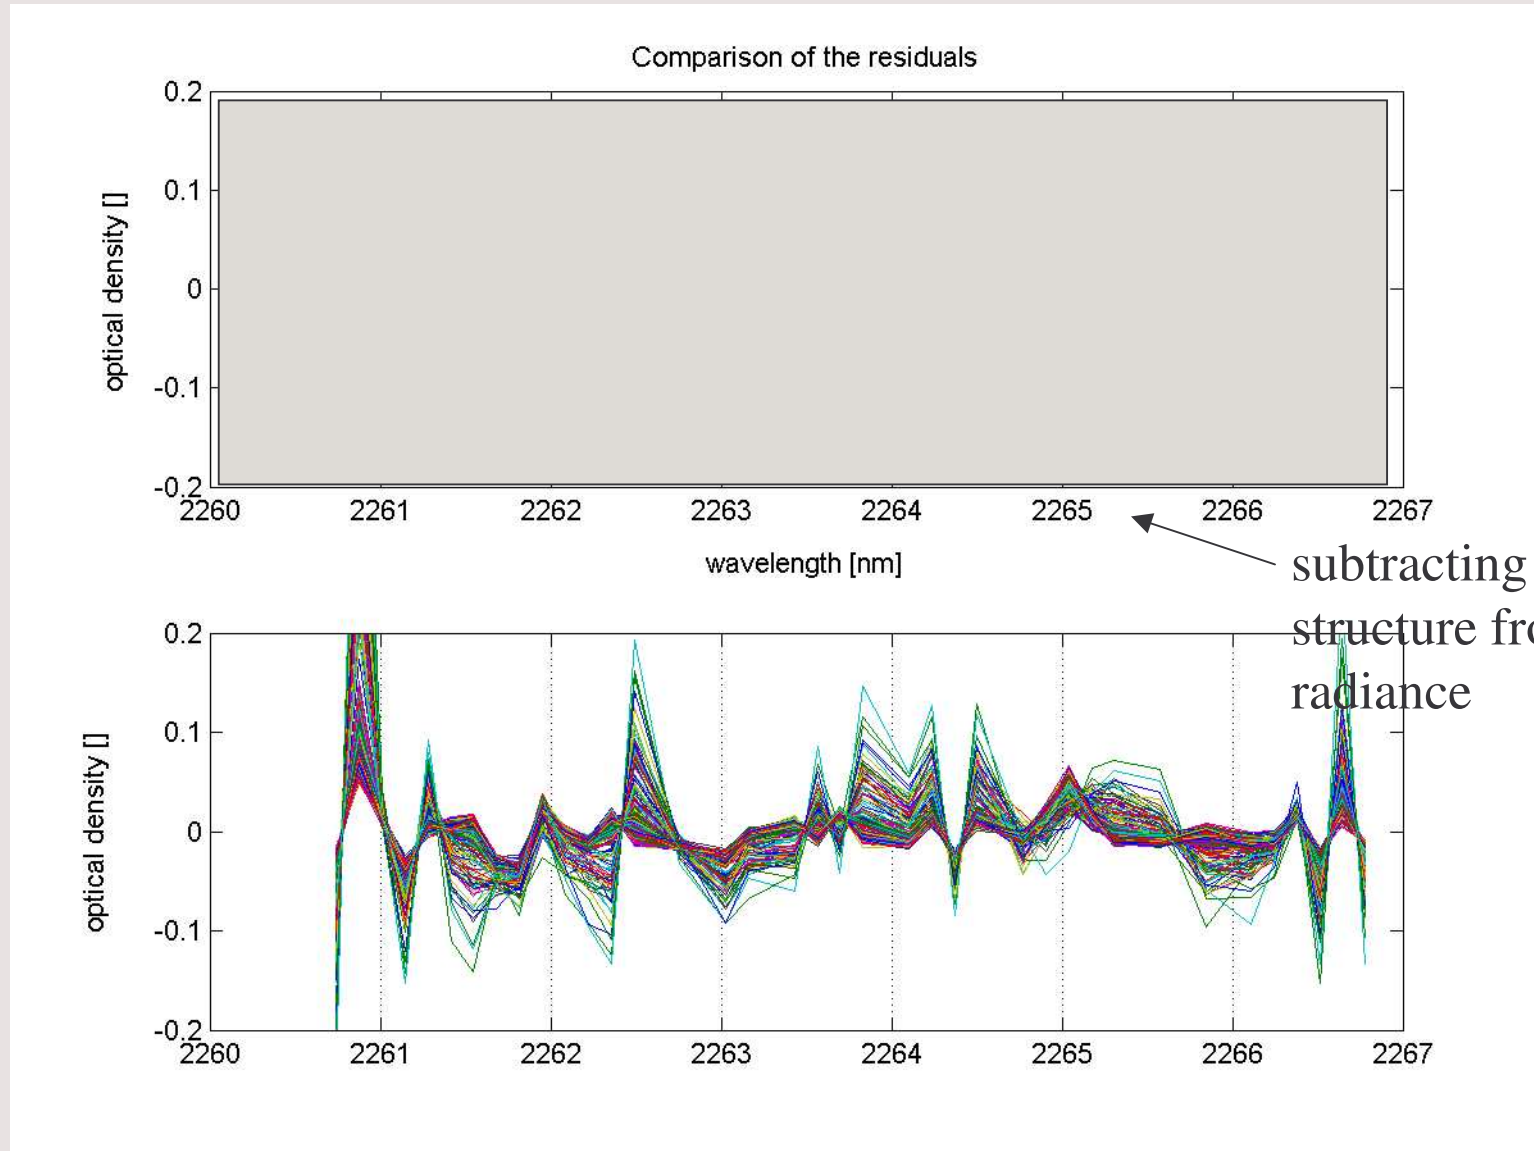

## Retrieval problems [2]

- Over the Mediterranean the radiance is quite low and no absorption structures are identifiable
  - However there is a spectral structure in these spectra (Why?)
  - Residuals are typically quite high and correlate with these structures!!
-

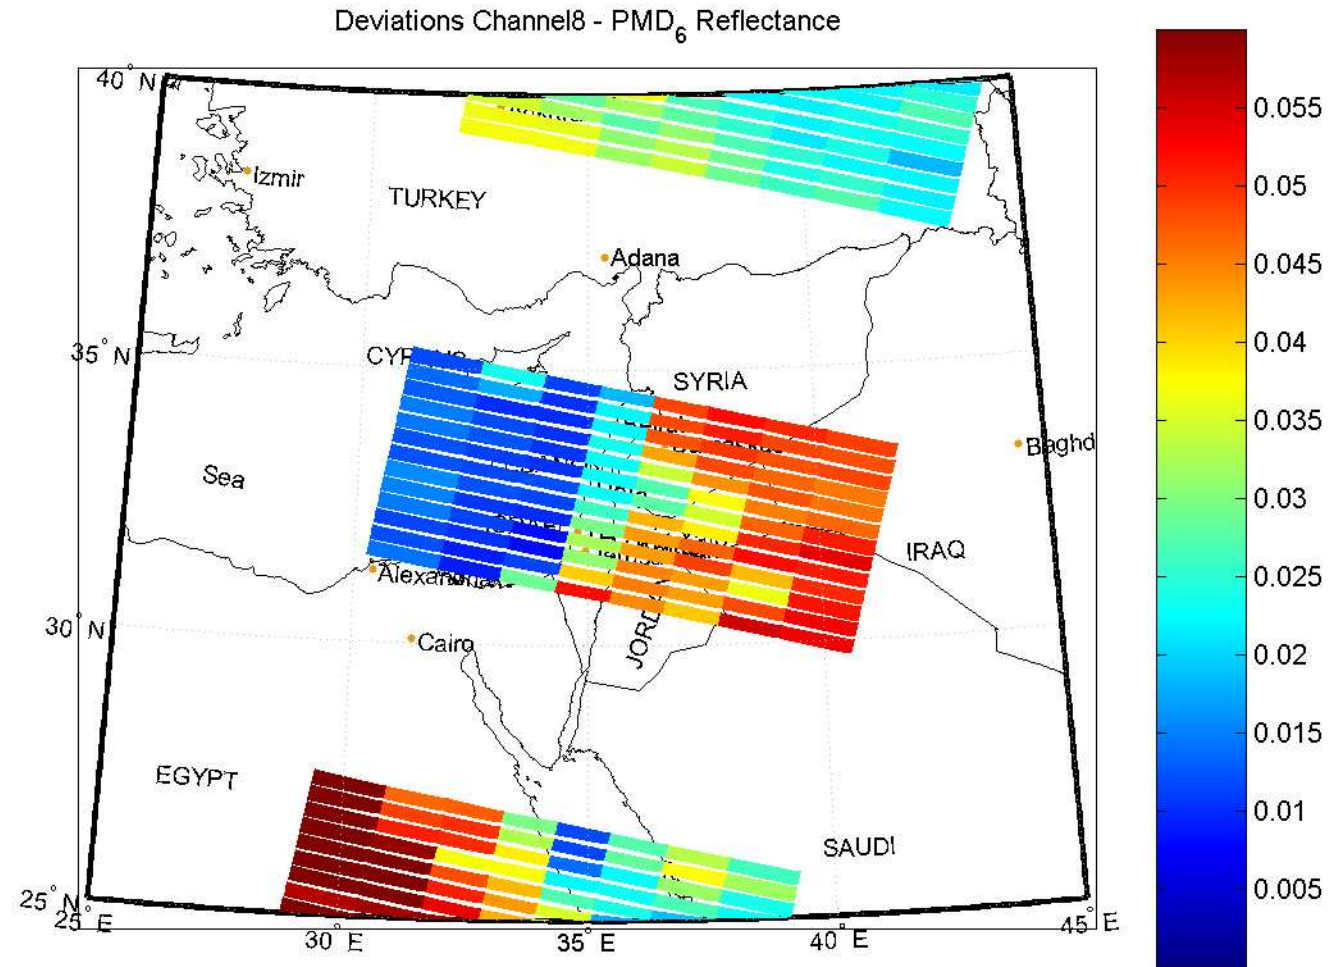

## Retrieval problems [2]

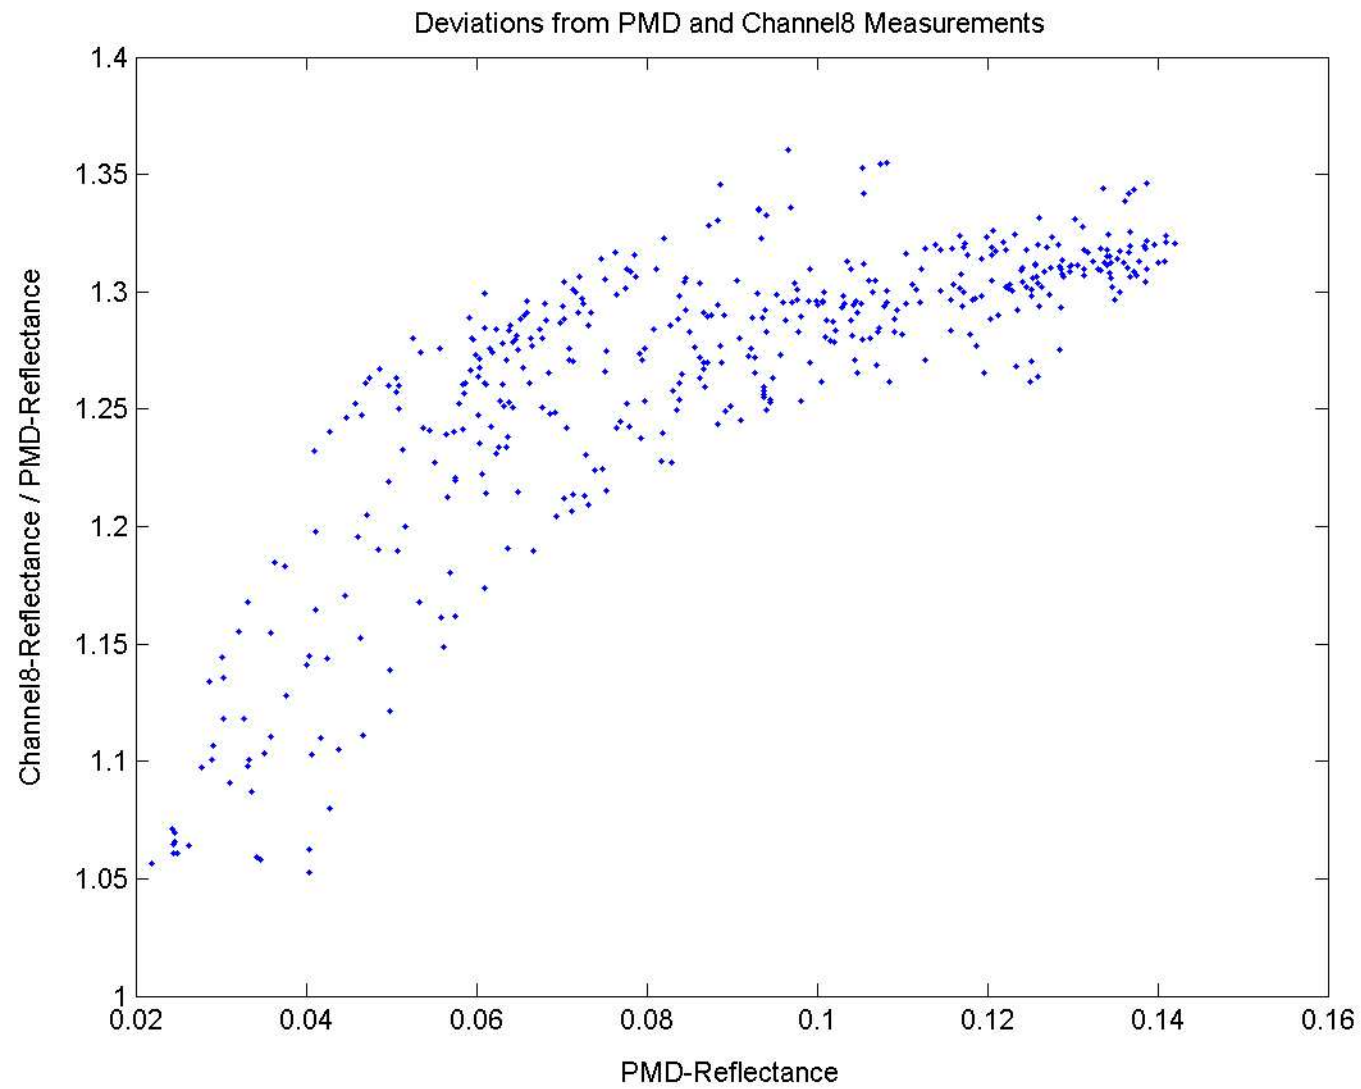

- Residuals consists of a strongly varying and a relatively stable part
  - Varying part due to an incorrect dark current correction (with spectral structure as seen before) ?!
  - Stable part cannot be explained by dark current or wrong absorber profiles, but by wrong sun reference or gain factors ?!
  - Retrieval over oceans possible (with low SZA)??
-

## Retrieval problems [3]

- Reflectances determined from  $\text{PMD}_6$  deviate from Channel 8 mean reflectances (same wavelength region)
  - PMD reflectance quite low (wrong reference?)
  - also indicates wrong dark current correction
-

# Conclusion & Questions

- Calibration still bad (will it improve, what will improve?)
  - Residual structures (at least the varying part) are time dependent (due to icing? problem solvable in the near future?)
  - Albedo over water surface at low SZA's too low for sensible retrieval (the same holds for ice)??
  - Reflecting properties of surfaces, clouds in the NIR totally different from UV/VIS
-

## Conclusion & Questions (2)

- use as little DOAS-fit parameters as possible (we try not to fit mean residuals but take them into account before DOAS fit)
  - CO absorption structures not identifiable with the naked eye (but the retrieval nearly always yields positive VCD's)
  - PMD – Channel8 comparison suitable for determining dark current offset?
-

# Near-Future plans

- Optimizing convolution parameters (voigt shape)
  - examining influence of changing atmospheric concentration-profiles, extreme temperature&pressure profiles
  - using elevation information
  - identifying CO
  - using relational database for results storage and management
-

The preliminary end...
