

# Global upper tropospheric/lower stratospheric water vapor from satellites

G.P. Stiller, S. Lossow, M. Kiefer, W. Read, K.H. Rosenlof, M. García-Comas, M.E. Hervig, G. Nedoluha, E.E. Remsberg, J.M. Russell III, T. Schieferdecker, L. W. Thomason, J. Urban, K.A. Walker, M. Weber, J.M. Zawodny

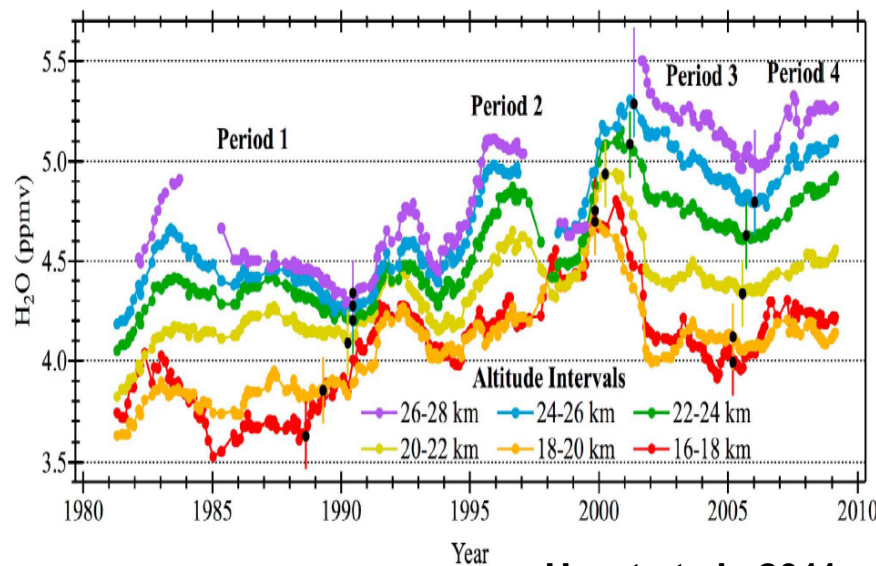

Institute for Meteorologie and Climate Research – Atmospheric Trace Gases and Remote Sensing

**HALOE tropical H<sub>2</sub>O time series,  
from Rosenlof and Reid, 2008**

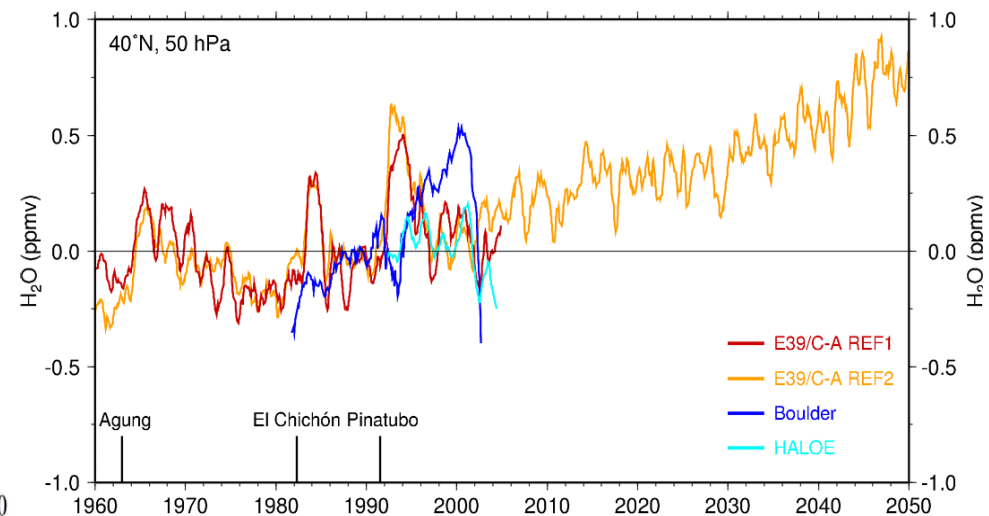

# Motivation

- Water vapor is the most powerful greenhouse gas in the atmosphere
- The temporal variation of lower stratospheric water vapor is not yet fully understood
- Water vapor transport into the stratosphere seems to be largely, but not fully ruled by the tropical tropopause temperatures

Hurst et al., 2011

Dameris et al.

# Motivation: Why is UTLS water vapor important?

Solomon et al., Science, 2010

## SPARC WAVAS-II satellite data quality assessment: Aims and scope

- Update of WAVAS-I report published in 2000 (SPARC report No. 2)
- Analysis of the quality of water vapor satellite records:
  - Compare satellite records **to ground-truth** (CFH, LIDAR, MW) measurements on basis of co-incident observations
  - Compare satellite records **among each other** on basis of co-incident observations; for special regions and latitude bands/seasons
  - Compare satellite records **on basis of climatologies**; collect available material and complete
  - Compare representation of **temporal variation** on basis of climatologies and within co-incident comparison to ground-truth instruments (seasonal, QBO, longer-term)
  - Compare **upper tropospheric specific humidity** from satellites (TES, IASI, AIRS, TOVS)
  - Compare available satellite data records on water vapor **isotopologues** (HDO,  $\delta D$ ) and compare to ground-truth observations
- General approach: review of literature completed by dedicated studies where necessary

# Examples

# Latitude cross sections of H<sub>2</sub>O

MLS v3

HALOE

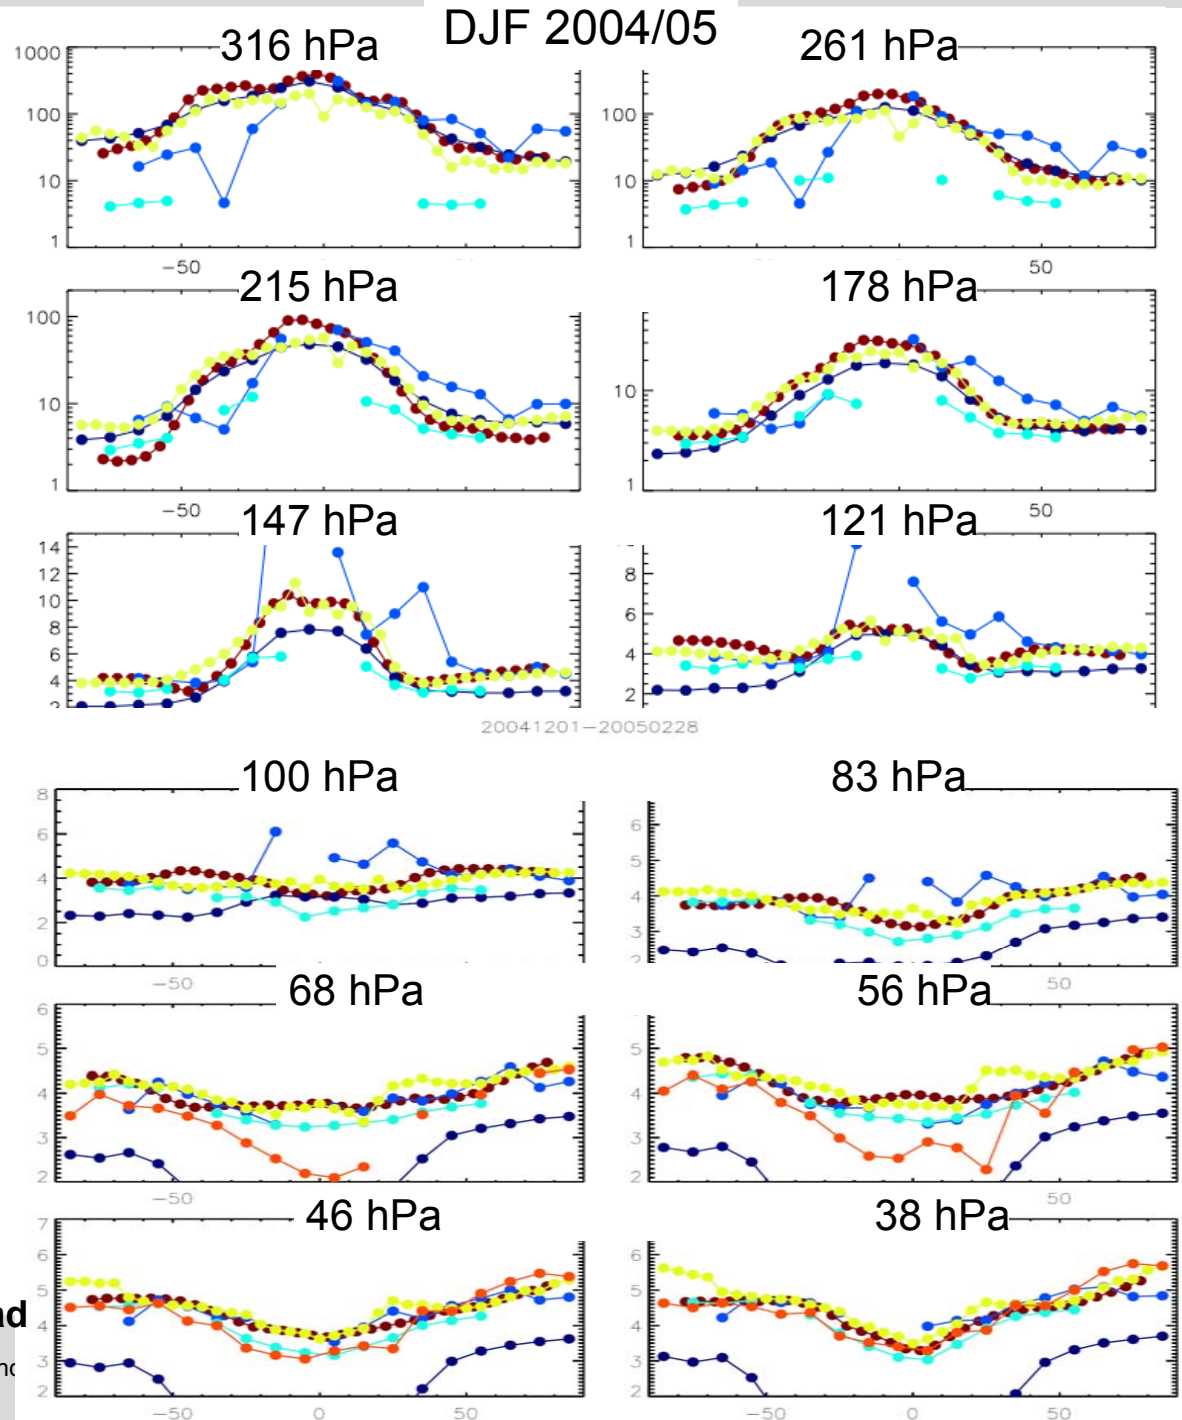

MIPAS

ACE-FTS

AIRS

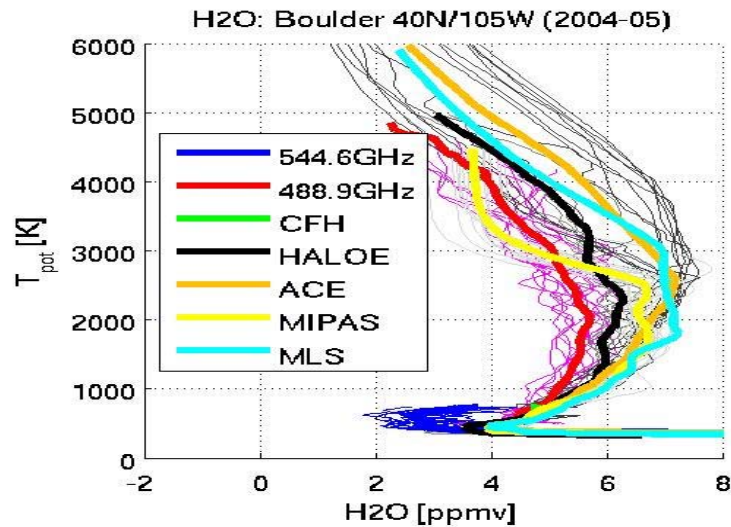

SMR

- HALOE is dry for most altitudes
- SMR has a pronounced dry bias in the tropics below 38 hPa
- Sparse statistics for ACE-FTS
- AIRS not to be used above 100 hPa
- MIPAS dryer than MLS below 200hPa and wetter around tropopause

# Confrontation of CCMs to observational data

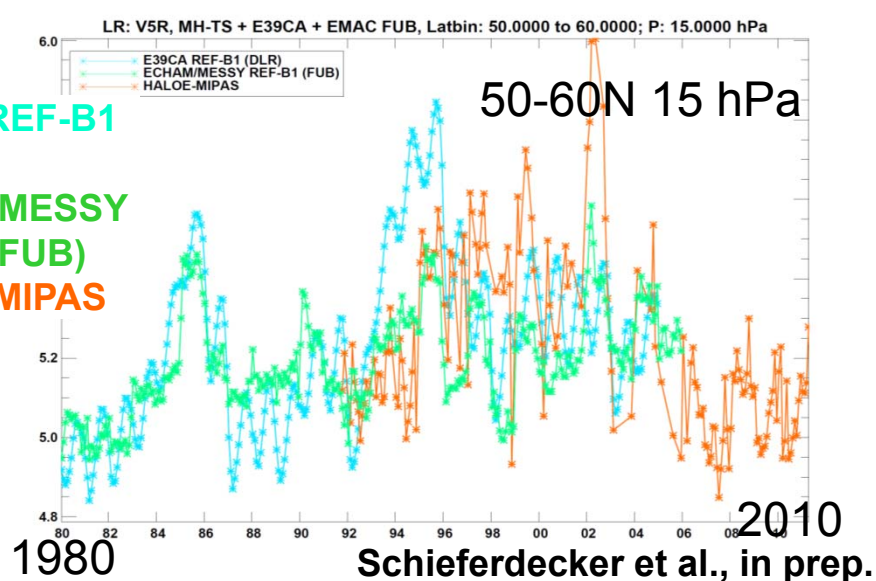

Kunze et al., 2010

1. Understanding of processes, here: WV transport through monsoon systems

2. Understanding of temporal variation and trends: no single trend in observational data; CCMs: check piecewise linear trends, ascent rates of the tape recorder, volcanic signals, etc.. How realistic are model predictions then?

# Future perspectives

- Satellite missions covering water vapor observation still in orbit:
- MLS
- ACE-FTS
- SOFIE
- SAGE III-ISS
- SMR
- AIRS
- TES
- IASI
- Most of them are aged missions with limited remaining lifetime
- In Europe: no plans for limb sounders before 2020

# Summary

- The last decade was a 'golden age' for global water vapor observation from satellites
- The SPARC WAVAS-II activity plans a thorough satellite data quality assessment
- Satellite data records have large biases (lat/alt dependent) and reproduce seasonality differently (amplitude and phase of the tape recorder)
- Water vapor isotopologues (HDO/ $\delta D$ ) shed light on condensation/freezing processes during TST of water vapor
- Three available data sets – ACE-FTS and MIPAS largely consistent in HDO, but disagree in  $\delta D$ .
- A gap of vertically resolved UTS water vapor observations is to be expected for the next decade

# Consistency of satellite records: tropics

H<sub>2</sub>O vapor 16-20 km 15°S-15°N

H<sub>2</sub>O vapor 16-20 km 15°S-15°N

- Large biases
- Strong variability in the amplitude of the tape recorder
- Data records agree much better after de-seasonalization
